Clustering, Informal Goals

Goal: Automatically partition **unlabeled** data into groups of similar datapoints.

Question: When and why would we want to do this?

Useful for:

- Automatically organizing data.
- Understanding hidden structure in data.
- Preprocessing for further analysis.
 - Representing high-dimensional data in a low-dimensional space (e.g., for visualization purposes).

Clustering

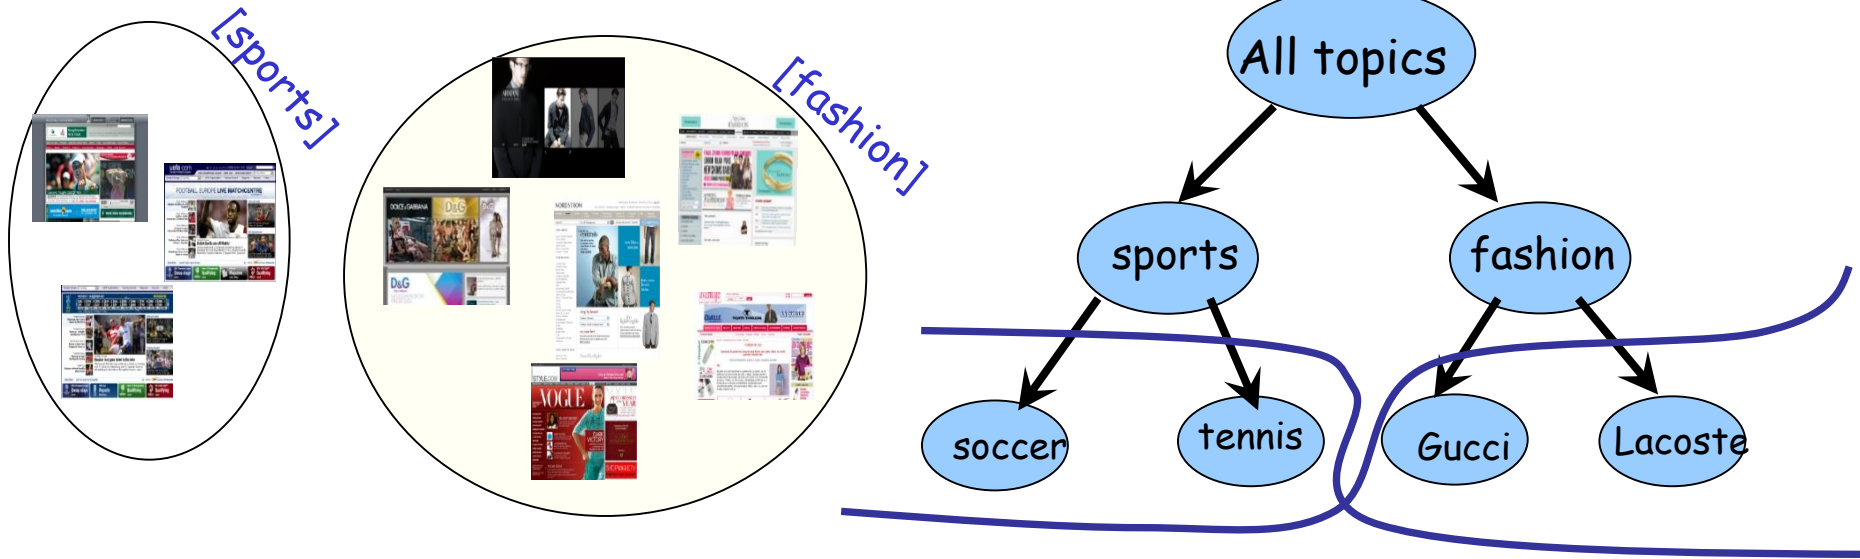

- Last time: Partitional objective based clustering
- Focused on k-means and k-means ++
 - Lloyd's method
 - Initialization techniques (random, furthest traversal, k-means++)
- Today: hierarchical Clustering.
 - Single linkage, Complete linkage

What value of k ???

- Heuristic: Find large gap between $k-1$ -means cost and k -means cost.
- Hold-out validation/cross-validation on auxiliary task (e.g., supervised learning task).
- Try hierarchical clustering.

Hierarchical Clustering

- A hierarchy might be more natural.
- Different users might care about different levels of granularity or even prunings.

Hierarchical Clustering

Top-down (divisive)

- Partition data into 2-groups (e.g., 2-means)
- Recursively cluster each group.

Bottom-Up (agglomerative)

- Start with every point in its own cluster.
- Repeatedly merge the "closest" two clusters.
- Different defs of "closest" give different algorithms.

Bottom-Up (agglomerative)

Have a **distance** measure on pairs of objects.

$d(x,y)$ - distance between x and y

E.g., # keywords in common, edit distance, etc

- Single linkage: $\text{dist}(C, C') = \min_{x \in C, x' \in C'} \text{dist}(x, x')$
- Complete linkage: $\text{dist}(C, C') = \max_{x \in C, x' \in C'} \text{dist}(x, x')$
- Average linkage: $\text{dist}(C, C') = \text{avg}_{x \in C, x' \in C'} \text{dist}(x, x')$

Single Linkage

Bottom-up (agglomerative)

- Start with every point in its own cluster.
- Repeatedly merge the "closest" two clusters.

Single linkage: $\text{dist}(C, C') = \min_{x \in C, x' \in C'} \text{dist}(x, x')$

Dendrogram

Complete Linkage

Bottom-up (agglomerative)

- Start with every point in its own cluster.
- Repeatedly merge the "closest" two clusters.

Complete linkage: $\text{dist}(S, T) = \max_{x \in S, x' \in T} \text{dist}(x, x')$

One way to think of it: keep max diameter as small as possible at any level.

Running time for Single and Complete Linkage

- Each algorithm starts with N clusters, and performs $N-1$ merges.
- For each algorithm, computing $\text{dist}(C, C')$ can be done in time $O(|C| \cdot |C'|)$. (e.g., examining $\text{dist}(x, x')$ for all $x \in C, x' \in C'$)
- Time to compute all pairwise distances and take smallest is $O(N^2)$.
- Overall time is $O(N^3)$.

In fact, can run all these algorithms in time $O(N^2 \log N)$.

If curious, see: Christopher D. Manning, Prabhakar Raghavan and Hinrich Schütze, Introduction to Information Retrieval, Cambridge University Press. 2008. <http://www-nlp.stanford.edu/IR-book/>

What You Should Know

- Partitional Clustering. k-means and k-means ++
 - Lloyd's method
 - Initialization techniques (random, furthest traversal, k-means++)
- Hierarchical Clustering.
 - Single linkage, Complete linkage
